

Part 2: Defining the Machine Learning Problem (car price prediction dataset)

This issue in the field of machine learning is a regression task aimed at predicting the selling price of a car based on its characteristics. The data set includes such as the year of manufacture, the number of kilometers travelled, the type of fuel, the type of transmission, the number of seats, the capacity of the engine, the maximum capacity, the distance travelled, and the date of ownership. The target variable is the selling price, and the model is expected to learn the relationship between these traits to accurately predict car prices
